

# **Eight Interesting Facts About Microprocessor and Microcontroller**

- A microprocessor is like the brain of a computer and requires external memory and components, whereas a microcontroller is a complete system with CPU, memory, and I/O in a single chip.
- Microprocessors are used in computers and laptops, while microcontrollers are used in embedded systems like washing machines, cars, and remote controls.
- Microcontrollers consume very low power and are suitable for battery-operated devices, while microprocessors consume more power.
- Microprocessors operate at higher speeds (GHz range), while microcontrollers operate at lower speeds (MHz range).
- Microcontrollers are cheaper due to integration, whereas microprocessors require additional components, increasing cost.
- Microcontrollers are ideal for real-time applications, while microprocessors are used for complex processing tasks.
- The first commercial microprocessor was the Intel 4004, developed by Intel in 1971.
- Microcontrollers are embedded in almost every modern electronic device, including smart TVs, cars, and wearable devices.
